

Charge

Network is becoming more and more important in the modern times. There are hundreds million of people studying, researching and playing with the Internet. However, we can't forget that there will be a lot of cost when the network is running. So charging from the users is necessary and of course reasonable.

The very very famous Southern Mountain high School in the City of Soft Sheep has such a network of education. There are 2^N users in total, which are numbered $1, 2, 3, \dots, 2^N$. These users are connected by routers and cables.

Users, routers, cables make a Full Binary Tree together. Each leaf (colored white) of the tree denotes a user, each non-leaf node (colored gray) denotes a router, each edge denotes a cable, see the following picture.

The charge mode of the network company in the city of Soft Sheep is quite strange, so called "Pairing Charging". It means that they charge from each two users i and j ($1 \leq i < j \leq 2^N$). Users can choose one mode of charge among A and B by themselves, so the cost that the company charge from the great school is relative to the mode of charging by each user. The total cost equals to the sum of the cost of each pair of users.

Some definitions:

- **Ancestor:** The root of the tree has no Ancestor, each ancestor of some other node Ancestors are father of this node and the father's Ancestor.
- **dominated Leaf:** The leaves dominate nothing, the leaves dominated by one non-leaf node are all the leaves dominated by the left and right child of this node.
- **Dist:** The shortest path between each pair of nodes in the tree.

For each pair of users i, j ($1 \leq i < j \leq 2^N$), first we find the LCA (Least Common Ancestor) of the two nodes named P , then let's consider the Dominated Leaves of P (the users assigned to P). We define n_A, n_B denoted the number of users choose A and B to charge in these Dominated Leaves.

Charging is following the rule below: (in the rule, $F(i, j)$ denotes the flux between i and j and will be

given.)

Charge Mode of i	change Mode of j		k	The final cost
A	A	$nA < nB$	2	$k * F_{i,j}$
A	B		1	
B	A		1	
B	B		0	
A	A	$nA \geq nB$	0	
A	B		1	
B	A		1	
B	B		2	

Since the total cost is relative to the mode of charging, the users in the great Southern Mountain School hope to minimize the cost by changing the way of charging. However, the company has recorded the mode that each user chose when they registered. So for each user i , if he/she wants to change the mode of charging, (change from mode A to mode B, or change from mode B to mode A), he/she must pay $\$C_i$ to the company to modify the record.

Your task is:

Given the mode the users chosen when they registered, and C_i , decide the mode to charge of each user to minimize the total cost (the cost of changing mode + the sum of the cost of the Pairing Charging).

Input

T [The number of test cases]

N [$N \leq 10$]

D1 D1 D2 ... DM [$M = 2^N$, $D_i = 0$ iff the mode user i chosen when he/she registered is A and $D_i = 1$ otherwise.]

C1 C1 C2 ... CM [the cost of changing the mode of each user, $0 \leq C_i \leq 500000$]

F(1,2) F(1,3) ... F(1,M)

F(2,3) F(2,4) ... F(2,M)

...

F(M-2,M-1) F(M-2,M)

F(M-1,M)

[The table above is the flux table description, $0 \leq F(i,j) \leq 500$]

[other tests]

Output

TheMinCost

[other tests]

Example

Sample Input:

```

1
2
1 0 1 0
2 2 10 9
10 1 2
2 1

```

3

Sample Output:

8

Hints:

Change the mode of the first user from mode B to mode A.
